1. Register Client Service Tree

To implement this service, we use the following services:

- **ClientExistsService**: uses an adapter to the database to validate if a client is registered.
- **AddressValidationService**: Uses the CTT external service to validate an address.
- **GeneratePasswordService**: Generates a random password with a specific size.
- **CreateClientService**: Uses an adapter to the database to create a new client, returns the new client number.
- **SendRegistrationMessageService**: Sends an email to the client with it's number and password. Uses a service named **SendEmailService** or **SendSMSService** to send the message as an email or SMS, depending on an argument that is passed.

2. Request Quotation Service Tree

To implement this service, we use the following services:

- **CalculateCoordinatesDistanceService**: Uses the Google Maps external service to calculate the distance (in km) between two sets of coordinates (latitude and longitude).
- **ObtainBestOfferService**: Compares the offers from the two transporters (A and Z) and returns the best offer and respective transporter. It invokes the transporters' services (**RequestQuotationTransporterAService** and **RequestQuotationTransporterZService**) which calculate the offer based on the parcels' weight and travel distance.
